Señor Doctor ARTURO CARPIO NEUROLÓGO CLINICO Cuenca.—

Quito, 14 de Diciembre de 1985.

Estimado Arturo:

He visto a la niña Sedillo, quien presentó a los 3 meses de edad crisis convulsivas tipo espasmos en flexión y un trazado por tí descrito de punta y polipunta onda lenta, a mi juicio compatible con trazado de ipearitmia fraccionado de sueño (inducido con Hidrato de Cloral).

Las crisis convulsivas persisten, pese a la medicación que se en cuentra tomendo con una cadencia de 4 a 5 diarias y caracterizadas por episodios de mirada fija y pérdida de conciencia por fracciones — de segundos. Desde al punto de vista tomográfico aprecio una separación del espacio interventricular, en el cual se asienta un quinto — ventrículo, Quiste del Septum Pellucidum.

Prednizona oral a randa de ACTH, es aconsejable mantener a la niña con 6 meses y el martenatento de 0.2 mg/kilo, por un periodo no menor ros efectos colaterales de cuando de sus drogas anticonvulsivantes. Con momento intervención inmediata del ACTH que podría precisar en algún vor vacuna doble, no triple. Creo que sería conveniente realizar a la niña Sedillo Crespo tra lo rescritate en base de ACTH (Actargel) a razón de 4 unidades ki analitica de laborateria de correspondiente.

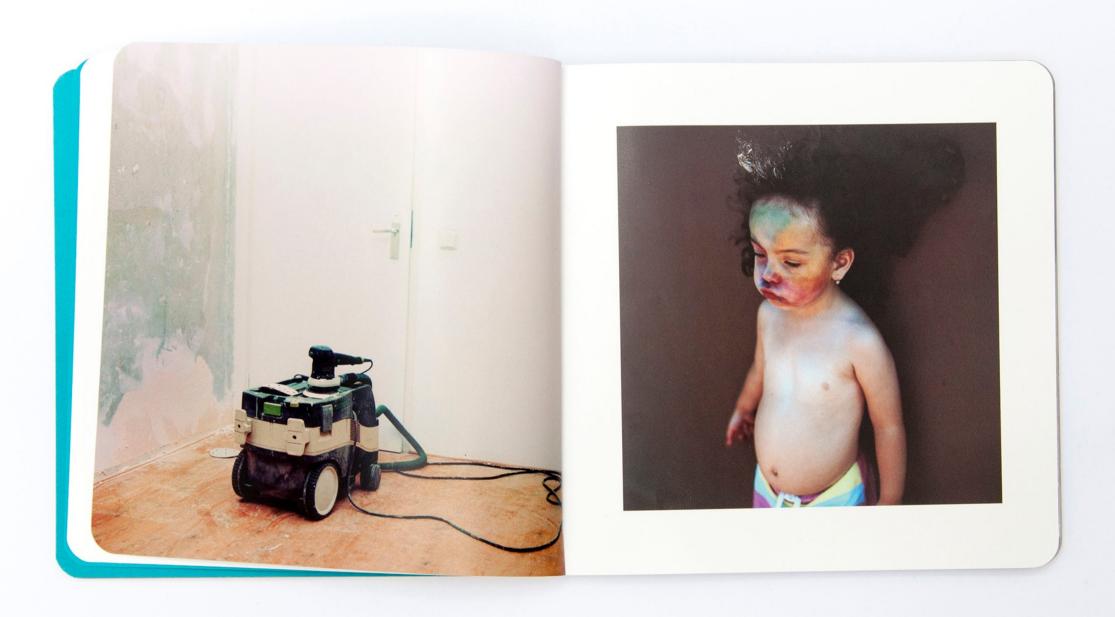

La la laborateria correspondiente.

Agradejiando por la atención que des a la presente

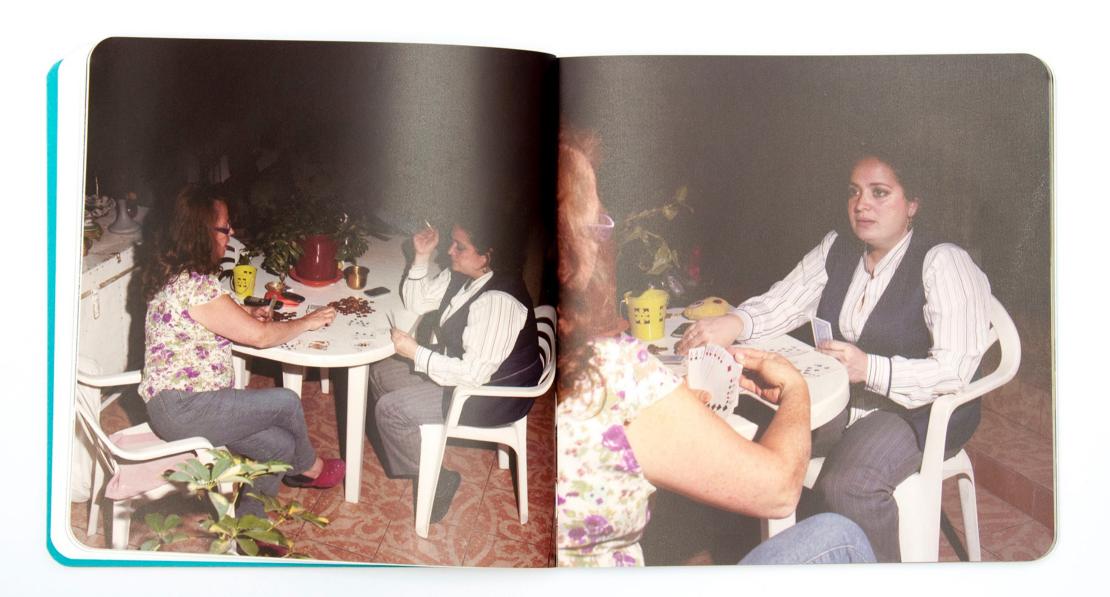

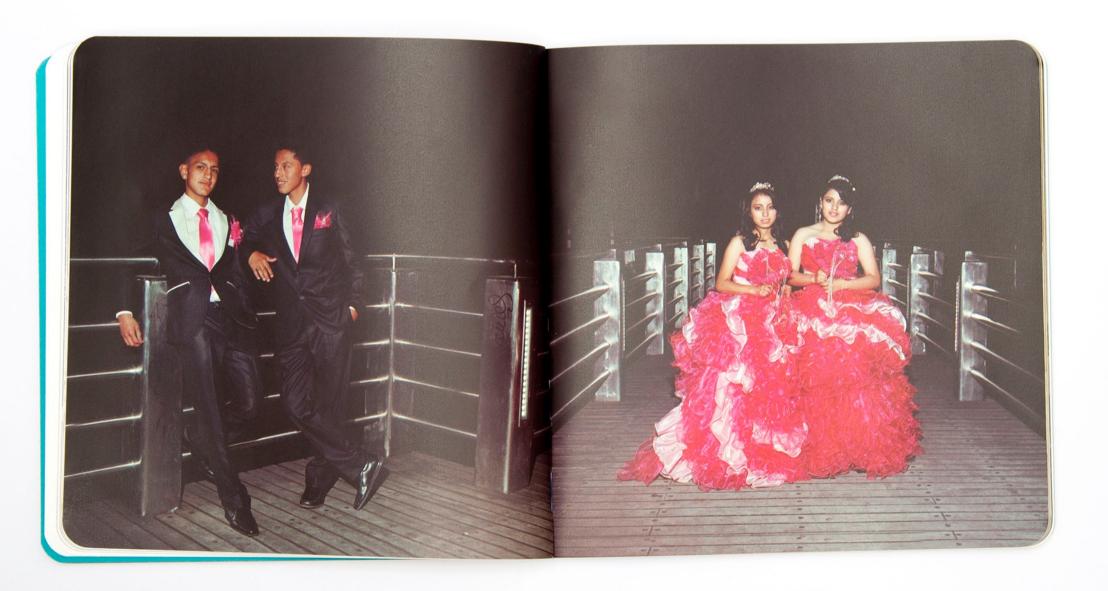

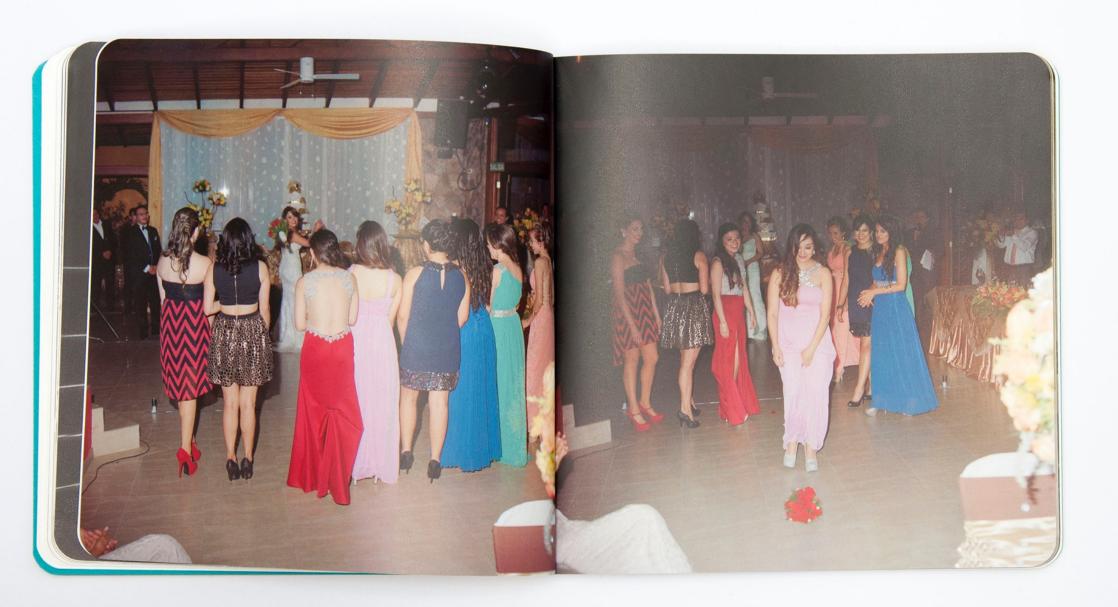

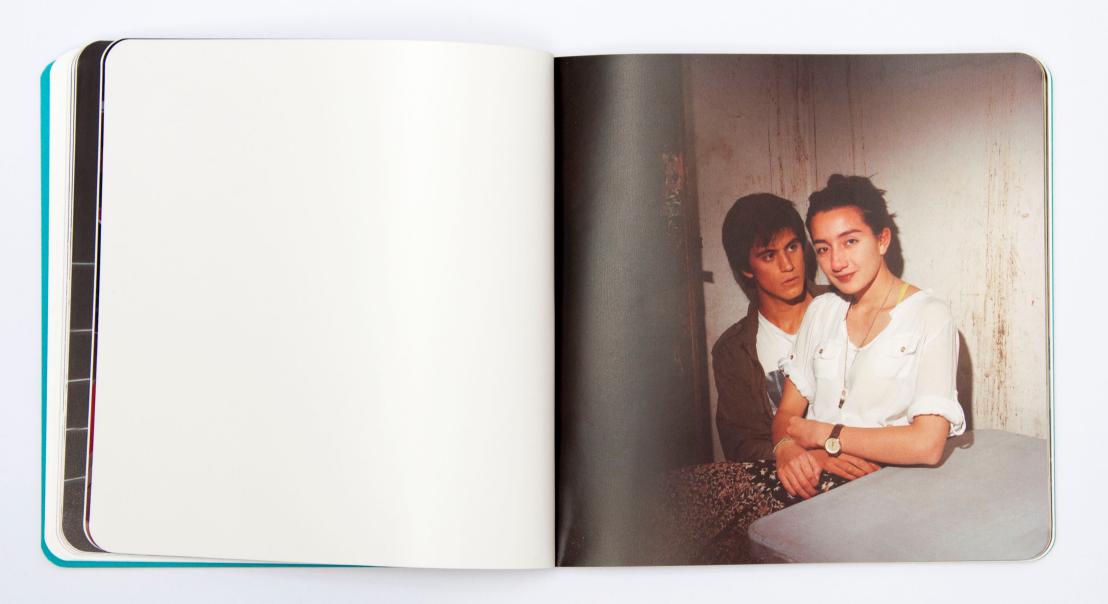

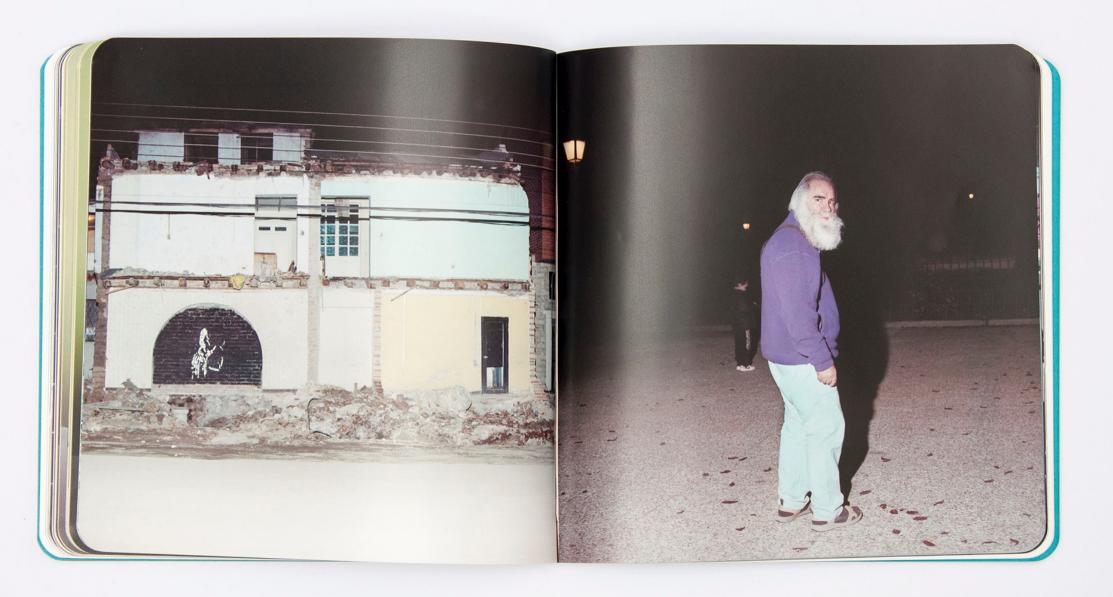

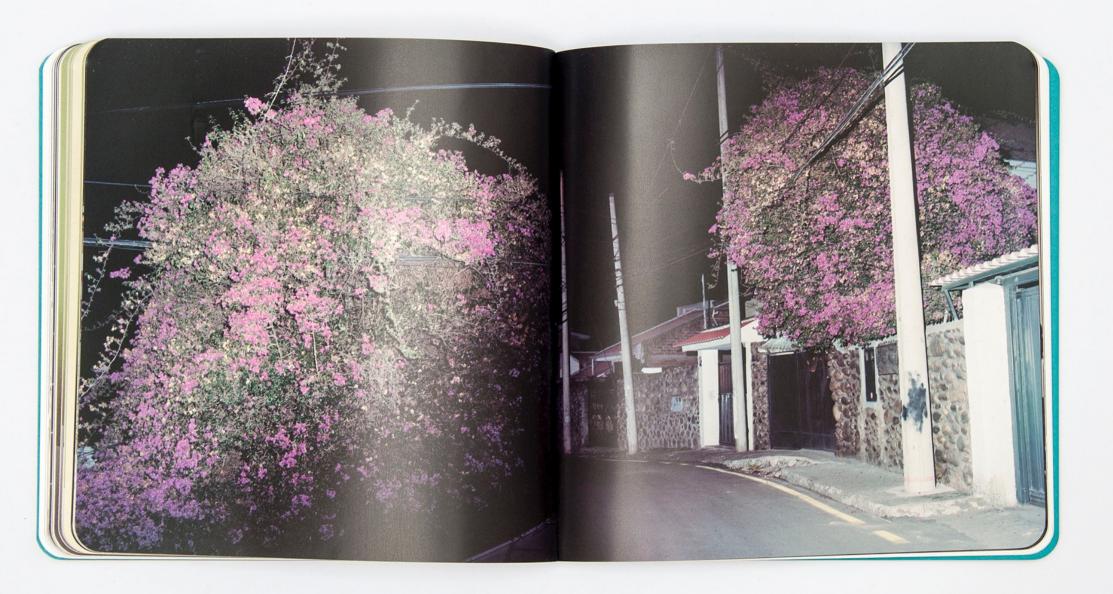

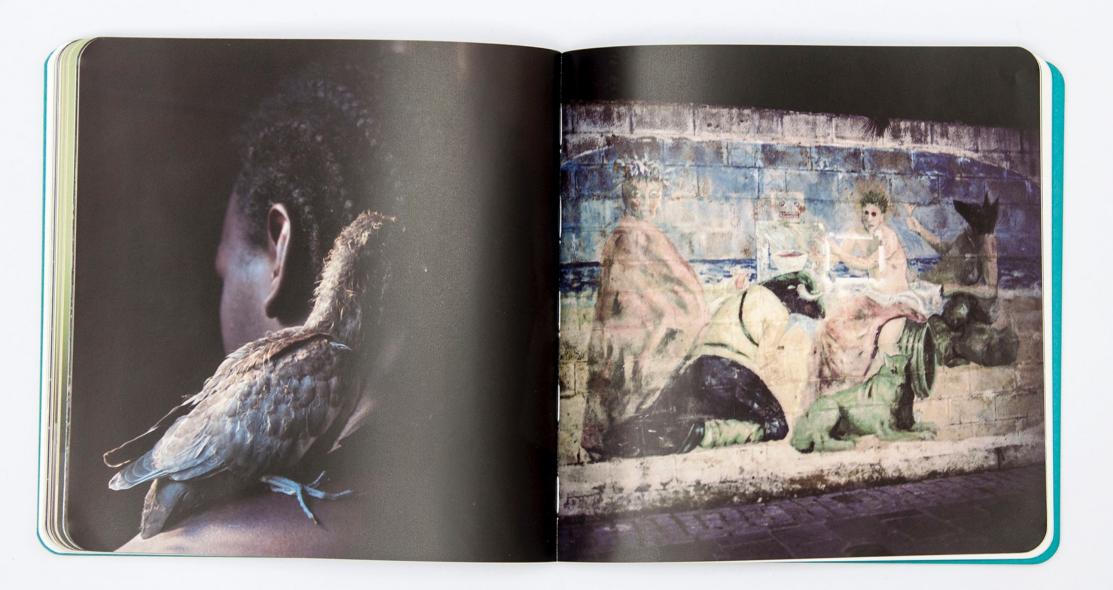

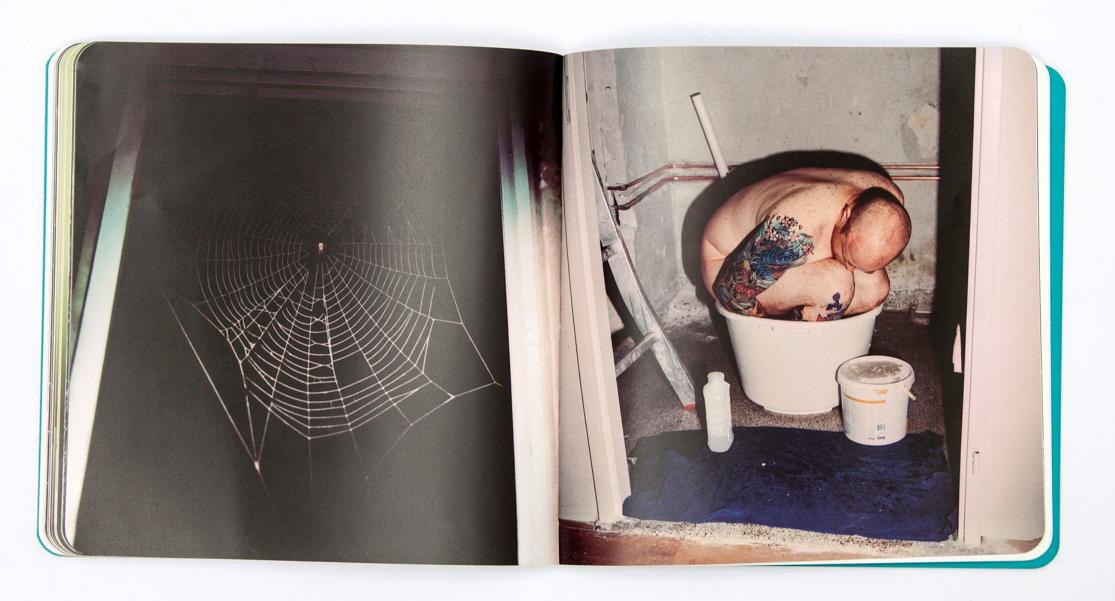

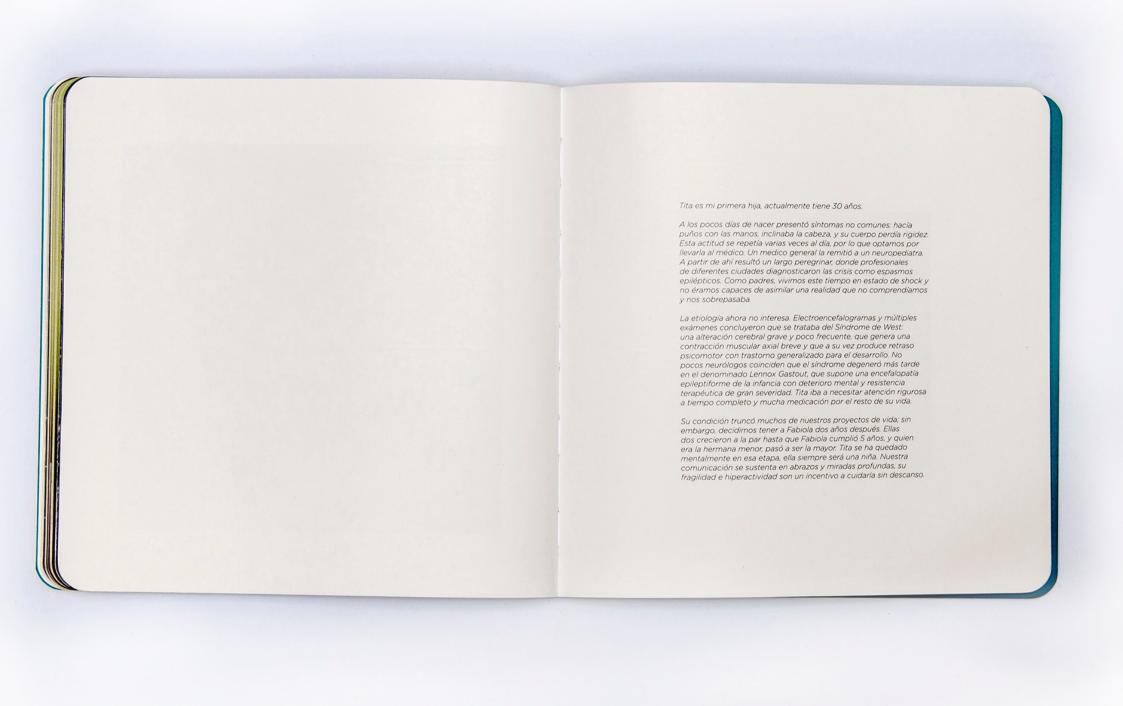

Tita is my first daughter. She is now 30 years old

A few days after her birth, she presented uncommon symptoms: she clenched her fists, bowed her head, and suddenly, her body lost strength. These symptoms were repeated several times a day, so we decided to take her to the doctor. A general physician referred her to a neurologist. From there it was a long journey, where professionals from different cities diagnosed her illness as epileptic seizure spasms. As parents, we lived this time in a state of shock and we were not able to digest a reality that we did not understand and it overwhelmed us

The etiology is not now important. Electroencephalograms and multiple tests concluded that Tita suffered from the West Syndrome, which consists of a serious and rare brain disorder that generates short, axial muscle contractions; this produces psychomotor retardation with pervasive development disorder. Some neurologists agreed that the syndrome later degenerated into the so-called Lennox Gastout, which is a childhood epileptic encephalopathy with mental deterioration and therapeutic resistance of great severity. Tita would need rigorous full time attention and much medication for the rest of her life.

Tita's condition truncated many of our life projects; however, two years later we decided to have Fabiola. These two girls grew up together until Fabiola turned 5 years old. By then, who was the younger sister became the oldest. Mentally Tita has stayed at the same age, she will always be a child. Since then, our communication is based on hugs and deep gazes. Her fragility and hyperactivity drive us forward into taking care of her without rest.
